Contents

Part I: Internal structure and stellar evolution

by RICHARD MONIER

1. The physical conditions in the interiors of stars:
 - Equation of state, hydrostatic equilibrium, equation of continuity
 - Virial theorem
 - Local Thermodynamical Equilibrium
 - Adiabatic coefficients
2. Sources and mechanisms of transport of energy in stars
 - Nuclear reactions, quantum treatment, nuclear reaction rates
 - Various nuclear reactions in stellar interiors
 - Third equation of stellar structure
 - Radiative transfer, Opacity
 - Convective transport
 - Conductive transport
3. Simple models of stars in equilibrium
 - Polytropes
 - standard model
 - Eddington luminosity, Chandrasekhar mass
4. Introduction to stellar evolution
 - The equations of stellar evolution.
 - Different zones of EOS.
 - Instable regions.
 - Evolutionary path.
 - The theory of the Main Sequence, relationship Mass-Radius, Mass-Luminosity
 - Evolution before the Main Sequence, Forbidden Hayashi zone.
 - Evolution on the Main Sequence.
 - Evolution after the Main Sequence for stars of different masses.

Part II: Radiative transfer and stellar atmospheres

by MARIANNE FAUROBERT

1. Radiation-matter interactions. Radiative opacities
2. Radiative transfer equation
3. Radiative acceleration of matter and radiative pressure
4. Equivalent width and formation of atomic lines
5. The grey atmosphere. Atmospheric modelling

1. Pulsations across the HR diagram
2. Oscillations and asteroseismology
3. Pulsation modes and identification
4. Pulsation mechanisms and physical phenomena induced by choc waves
5. Different types of stellar pulsators and properties
6. Light curves, radial velocities. Circumpolar and space observations
